**Abstract**

Gastrointestinal stromal tumors represent a heterogeneous group of mesenchymal tumors that can develop throughout the gastrointestinal tract. We present the clinical case of a patient with such malignancies occurred in the proximal jejunum and clinically manifested by a severe digestive hemorrhage with hemorrhagic shock and severe post-hemorrhagic anemia. Pre-operative diagnosis was possible only through the Entero-MRI. The evolution was favorable after surgical extirpation. It's being discussed particular aspects of this lesion's entity and post-operative optimal attitude in this case.

Key words: gastrointestinal stromal tumors, lower gastro-intestinal bleeding, Entero-MRI
